APPENDIX E – Cost Estimates	56

## I. Introduction

To improve the City of Naples infrastructure and to protect the traffic signal system from damage during hurricanes and tropical storms, the City has been replacing span-wire and concrete pole traffic signal systems. Questions arose whether the remaining traffic signals needing mast arms are still warranted considering today's traffic data, or whether other forms of traffic control may offer a more effective solution. Therefore, *ADEAS-Q* was tasked to evaluate recent traffic volumes, survey data, crash data, aesthetics, and multi-modal access and to determine whether the existing traffic signals are still the best design alternative. Other options evaluated included stop-control and roundabouts. This task included developing preliminary designs, public education, outreach, cost estimates, and developing an evaluation matrix to help prioritize the recommended improvement for each location.

The four intersections under consideration are:

- Harbour Drive & Crayton Road
- Fleischmann Boulevard & 10<sup>th</sup> Street North
- 10<sup>th</sup> Avenue South & 9<sup>th</sup> Street South
- Broad Avenue South & 8<sup>th</sup> Street South

Each intersection currently operates with a single motor vehicle lane in each direction with left-turn lanes and/or bicycle lanes at some locations. Alternative forms of traffic for intersection control each were considered. A public workshop was conducted as part of this evaluation. Evaluation factors included traffic operations, pedestrian and bicycle access, safety, rightof-way availability, utility impacts, and public feedback. Preliminary cost estimates were also prepared.

This report summarizes the findings of this evaluation for the four intersections listed. A fifth span-wire intersection located at Mooring Line Drive & Crayton Road was previously evaluated and recommended for conversion to a roundabout by Alternative Street Design in a technical memorandum dated July 24, 2015. A copy of that technical memorandum is provided in

= Study Intersection

Appendix A. This report does not reevaluate this intersection, but does reference it for comparison to the four study intersections. However, based on a cursory review of the data collected and analysis completed, ADEAS-Q does generally concur that a roundabout may be justified at that location.

## II. Traffic Signal Warrants

Traffic counts were collected by city staff at each of the four study intersections on a weekday in February 2017 during the afternoon peak hours. This PM peak-hour count was seasonally adjusted to produce year 2017 peak-season, peak-hour traffic volumes. To evaluate the appropriateness of the existing traffic signals at the four study intersections, a screening evaluation of the peak-hour traffic volumes was made relative to the traffic signal warrants defined in the *Manual for Uniform Traffic Control Devices* (MUTCD). Warrant 1A, the eight-hour volume warrant, is the most likely to be referenced at these locations and was used for the comparison. While a complete signal warrant analysis requires at least eight hours of traffic count data, an estimation was made of the likelihood for each intersection to satisfy the eight-hour warrant using the one available hour of count data and the typical daily variation patterns in traffic.

The figure below summarizes the findings of this screening evaluation. The black dashed line represents the eight-hour warrant threshold defined in the MUTCD. Based on typical daily volume variation patterns, the green dashed line estimates the volume threshold for the peak one-hour that would indicate the intersection might meet the defined eight-hour warrant for eight hours. Intersections within the green box may meet the eight-hour warrant, with the likelihod increasing with distance from the dashed lines.

Other Traffic Signal Warrants

- Daily intersection volumes (8-hour, 4-hour, and 1-hour time periods)
- Number of crashes severity of crashes also should be considered
- Amount of foot traffic
- School crossings, coordinated signal systems, road network, nearby grade crossings
- Combination of factors above

Meeting signal volume warrants does not necessarily mean that a signal is the preferred alternative, but intersections that do not meet signal warrants are likely not appropriate for a traffic signal. The following two study intersections are currently signalized even though they do not appear to meet minimum volume warrants:

- Fleischmann Boulevard & 10<sup>th</sup> Street North
- Broad Avenue South & 8<sup>th</sup> Street South

However, it should be noted that there is a significant variation of traffic volumes in Naples, which includes a general increase of traffic around the Christmas shopping season. This factor potentially may have contributed to the previous need for signalization at these two locations listed.

## III. Analysis and Recommendations

The traffic volumes collected were evaluated for operations under the following potential configurations:

- 1. Replace span-wire signal with mast arm signal
- 2. Convert to all-way stop control (AWSC)
- 3. Convert to two-way stop control (TWSC), where feasible with traffic volumes
- 4. Convert to single-lane roundabout

Configurations 1, 2, and 3 assume that existing bicycle lanes, sidewalks, and crosswalks are retained. Configuration 4 assumes the sidewalks and crosswalks are added to all legs of the roundabout, and that bicycle accommodations are included where bicycle lanes exist.

Traffic volumes were analyzed using 2010 Highway Capacity Manual methodology using *Synchro* software for configurations 1, 2, and 3, and using the Roundabouts Guide (FHWA, 2010) methodology for configuration 4. Vehicle delay, level of service (LOS), and volume-to-capacity (V/C) ratio were reported for each intersection configuration. Appendix C provides the traffic operation analysis worksheets.

To compare expected safety performance of the different configurations, typical crash modification factors (CMFs) were derived from the Federal Highway Administration's (FHWA) CMF Clearinghouse with guidance provided by the Florida Department of Transportation (DOT) and Oregon DOT. CMFs quantify the relative number of crashes that may be expected with a change in configuration. A value of 1.0 indicates no change, a value less than 1.0 indicates an expected crash reduction, and a value greater than 1.0 indicates an expected increase in crashes.

## **Crash History**

A review of the available crash data provided by the City was undertaken for each subject intersection. Data available from February 2, 2007 – February 2, 2017 was provided, which represents 10 years of data.

Typically, traffic signals have higher rates of left-turn and rear-end types of crashes versus other forms of intersection traffic controls. Surprisingly, there was only a total of 34 traffic crashes combined for the four intersections. Provided below is a summary by each intersection:

- Fleischmann Blvd & 10<sup>th</sup> Street: 8 crashes
- Harbour Drive & Crayton Rd: 7 crashes
- 8<sup>th</sup> Street & Broad Ave South: 10 crashes
- <u>9<sup>th</sup> Street & 10<sup>th</sup> Ave South: 9 crashes</u>

Total = 34 crashes

Part of the reason for the low crash rates may be that each local roadway is a relatively "low-speed" facility, which allows for more reaction time and generally reduces the severity of crashes. However, it should be noted that 40% of the crashes at 8<sup>th</sup> Street & Broad Avenue resulted in injury, which may be considered a high percentage provided the location.

CRASH LOCATION	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	Total
FLEISCHMANN & 10TH ST	0	1	2	0	2	0	0	0	2	1	0	8
HARBOUR & CRAYTON RD	0	0	1	0	1	1	2	0	2	0	0	7
8TH ST & BROAD AVE S	0	1	5	1	0	1	1	0	1	0	0	10
9TH ST & 10TH AVE S	0	0	2	1	1	1	0	0	1	3	0	9
TOTAL	0	2	10	2	4	3	3	0	6	4	0	34

## Number of Crashes by Year

The following sections summarize the findings of the analysis for each specific intersection, including a description of the basis for recommendation.

## Harbour Drive & Crayton Road

The table below provides a comparison of vehicle operations for each configuration at the intersection of Harbour Drive & Crayton Road.

	Vehicle	Level		
	Delay	of	Volume/Capacity	
Configuration	(s)	Service	Ratio	CMF
1. Replace signal <sup>A</sup>	12.3	В	0.46	1.00
2. All-way stop <sup>A, C</sup>	18.4	С	0.68	0.61
3. Two-way stop <sup>A</sup>		Traffic	volumes too high	
3. Roundabout <sup>B</sup>	9.1	А	0.50	0.22

A: HCM 2010 Analysis (Synchro) B: 2010 FHWA Roundabouts Guide Methodology

C: Existing lane geometries assumed

This intersection currently has left-turn lanes and a large rightturn flare in the northbound direction, which creates a large footprint and inefficient use of public right-of-way. Crosswalks have recently been provided for each approach, but there is no pedestrian signalization or signage.

Bicycle activity was observed at the intersection and a growth of bicycle activity has been reported in recent years. Crayton Road is adopted with truck restrictions, but several trucks were observed using this facility. Several vehicles were also observed to run the red light. Similar observations were observed also at the intersection of Crayton Road & Mooring Line Drive during this evaluation.

The roundabout configuration provides the lowest delay and the safest performance expected at this intersection. A roundabout appears to be feasible without right-of-way impacts and without significant impacts to public utilities. A roundabout may also provide more comfortable mobility for people walking and bicycling via reduced vehicle

speeds through the intersection. Given these considerations, a

roundabout is recommended as the preferred configuration of the intersection of Harbour Drive & Crayton Road. However, an all-way stop control or a traffic signal are still feasible options.

## Fleischmann Boulevard & 10<sup>th</sup> Street North

The table below provides a comparison of vehicle operations for each configuration at the intersection of Fleischmann Boulevard & 10<sup>th</sup> Street North.

	Vehicle	Level		
	Delay	of	Volume/Capacity	
Configuration	(s)	Service	Ratio	CMF
1. Replace signal <sup>A</sup>	9.4	A	0.28	1.00
2. All-way stop <sup>A, C</sup>	9.5	A	0.36	0.61
3. Two-way stop <sup>A</sup>	6.2	A	0.22	1.52
3. Roundabout <sup>B</sup>	6.0	А	0.26	0.22

A: HCM 2010 analysis (Synchro) B: 2010 FHWA Roundabouts Guide methodology

C: Existing lane geometries assumed

This intersection currently prohibits the southbound through movement from the Coastland Center Mall onto 10<sup>th</sup> Street. It was reported that this was done to calm traffic through the Lake Park neighborhood following the mall's expansion. However, some vehicles were observed violating this prohibition. The existing signal is split-phased with northbound and southbound movements moving separately. This creates additional delay at the intersection.

The intersection does not currently appear to meet traffic volume signal warrants. Twoway stop control, with stop signs for the 10<sup>th</sup> Street mall access and Fleischmann Boulevard as the through street would typically operate well, but may result in a crash increase. All-way stop control would also operate relatively well, and would be expected to result in fewer crashes than a signal or two-way stop control.

The roundabout configuration may provide the least delay and the safest performance. A roundabout appears to be feasible with minor right-of-way impacts to the shopping center, and without significant impacts to public utilities. A roundabout may also provide comfortable mobility for people walking and bicycling. However, a roundabout would necessitate the southbound through movement from the mall to be allowed.

Given these considerations, a roundabout is the recommended preferred configuration for this intersection. However, the need for modifications is a lower priority than other

intersections evaluated. Coordination with the mall to permit reconstruction of the driveway to best match the roundabout design would be needed. Stop control or keeping a traffic signal are still feasible options.

## 10<sup>th</sup> Avenue South & 9<sup>th</sup> Street South

The table below provides a comparison of vehicle operations for each configuration at the intersection of 10<sup>th</sup> Avenue South & 9<sup>th</sup> Street South.

	Vehicle	Level		
	Delay	of	Volume/Capacity	
Configuration	(s)	Service	Ratio	CMF
1. Replace signal <sup>A</sup>	57.7	E	1.10	1.00
1A. Add WBL+NBR lanes <sup>A</sup>	14.3	В	0.63	0.89
1B. Add WBL lane <sup>A</sup>	28.4	С	0.94	0.89
2. All-way stop <sup>A</sup>	256.6 <sup>C</sup>	F	1.93	0.61
3. Two-way stop		Traffic	volumes too high	
4. Roundabout <sup>B</sup>	20.3	С	0.84	0.22

A: HCM 2010 analysis (Synchro)

B: 2010 FHWA Roundabouts Guide methodology

C: Stop delay is highly variable where V/C greatly exceeds 1.00

The intersection is constrained by narrow public rightof-way, and a modern roundabout here would likely need property acquisitions at all four corners. This condition is further exacerbated with the intersection as a preferred truck route. A graphic showing truck routes in the City is provided in Appendix B. Several different public and private utilities are also located directly next to the existing pavement.

This intersection experiences unusual turning movements. The predominant traffic patterns are between the east leg and the south leg to serve traffic traveling around the adjacent bayfront. These turning movements are typically not more advantageous for a roundabout versus other alternatives, but a roundabout could adequately serve the demand here.

Given the traffic patterns and the existing congestion at the intersection, the addition of potential turn lanes together with a signal replacement was explored. The signalized intersection is at or over capacity during the peak hour, and operations would benefit from the addition of a westbound left-turn lane and/or a

northbound right turn lane to channelize the predominant movements. But, the northbound right-turn lane is not ideal as right-turn lanes create multi-modal complications and are typically not a preferred option in redeveloping urban neighborhoods.

Given these considerations, replacement of the signal with the addition of a westbound left-turn lane is the recommended alternative for the intersection of 10<sup>th</sup> Avenue South & 9<sup>th</sup> Street South. Signal poles should be placed so as not to preclude a possible northbound right-turn lane. Pedestrian signals should be provided on all intersection legs and should provide adequate mobility and safety for people walking. New on-street parking located on 10<sup>th</sup> Avenue South in front of the redevelopment project was also explored.

## Broad Avenue & 8th Street South

The table below provides a comparison of vehicle operations for each configuration at the intersection of Broad Avenue & 8<sup>th</sup> Street South.

	Vehicle	Level		
	Delay	of	Volume/Capacity	
Configuration	(s)	Service	Ratio	CMF
1. Replace signal <sup>A</sup>	10.8	В	0.47	1.00
2. All-way stop <sup>A</sup>	12.0	В	0.56	0.61
3. Two-way stop <sup>A</sup>	4.8	A	0.23	1.52
3. Roundabout <sup>B</sup>	6.4	A	0.36	0.22

A: HCM 2010 analysis (Synchro)

B: 2010 FHWA Roundabouts Guide methodology

The two-way stop control and roundabout configurations result in the lowest delay at this intersection. Two-way stop control, with stop signs for 8<sup>th</sup> Street South would typically operate well, but may result in a crash increase. A roundabout may be the safest alternative, but would require either property acquisition at the two north corners or a realignment of Broad Avenue

to the south, which would result in higher construction costs. A roundabout would also impact stormwater utilities, resulting in higher construction costs. A significant water pipe/tunnel is located along Broad Avenue just south of the roadway.

Operating and maintenance costs would be reduced by removing the traffic signal. Typically, a traffic signal costs about \$3,000-\$5,000 a year to maintain. Traffic signal replacements cost several hundred thousand dollars and are required every 20-30 years. Hence, there are lower capital and operating cost savings by being able to convert a traffic signal to stop-control, where feasible.

The all-way stop control and traffic signal configurations result in slightly higher vehicle delay than the two-way stop control or roundabout configurations, but the relatively low traffic volumes still result in a good level of service (LOS B). The intersection does not currently appear to meet signal volume warrants. All-way stop control would result in reduced delay to pedestrians crossing the street as compared to a signal.

Given these considerations, all-way stop control is recommended as the preferred configuration at the intersection of Broad Avenue & 8<sup>th</sup> Street South.

City of Naples Streets & Stormwater Department

*Note*: During the observations traffic was occasionally observed backing up from the adjacent intersection of Broad Avenue & 9<sup>th</sup> Street. This is due to the existing configuration of 9<sup>th</sup> Street as the north-south through street, thus requiring eastbound traffic on Broad Avenue to stop and ensure that southbound traffic on 9<sup>th</sup> Street clears the intersection before proceeding, even though a vast majority of southbound traffic turns right. A revised control at Broad Avenue & 9<sup>th</sup> Street that converts the intersection to a three-way stop may improve operations

in this corridor. Then the eastbound traffic would not need to wait for the southbound traffic to turn before proceeding. The enclosed figure depicts a possible reconfiguration of the intersection.

## IV. Public Outreach

A public workshop was conducted on Thursday, April 13, 2017 regarding the "spanwire" intersection evaluation. Approximately 30 interested stakeholders attended this workshop together with City staff representatives. The workshop was conducted at the Naples City Council Chambers from 4:00-7:00 PM. The attendees were provided information and were able to discuss their questions/comments/concerns with City staff representatives. The interaction overall was informative and constructive.

It was observed that there is an ongoing "learning curve" within the City of Naples regarding the general technical performance of roundabouts. Participants clearly expressed "favorable" or "unfavorable" opinions of roundabouts, many times prior to reviewing the technical information provided for each location. A copy of the comment forms from the public workshop is provided in Appendix D.

The City has expanded education efforts with the recent installation of the Central Avenue roundabouts. Several different public information activities, as well as educational material on the City's website, have been provided as people locally are becoming more familiar. It is suggested that the City of Naples continue these efforts regarding the technical pros/cons of modern roundabouts.

## V. Findings

An evaluation of traffic operations, walking and biking considerations, expected safety performance, right-of-way, and public service utilities was performed at each of the four study intersections. A fifth intersection located at Mooring Line Drive & Crayton Road was previously evaluated and recommended for conversion to a roundabout. This memorandum does not reevaluate that intersection, but does reference it for comparison to the four study intersections.

These recommendations are intended to optimize performance for vehicles, pedestrians, and bicyclists, to improve safety, to be accommodated within existing right-of-way, to be cost effective, and to avoid impacts to significant utilities. The following evaluation matrix summarizes the considerations for each study intersection.

Based upon this review, a set of preliminary recommendations was developed for the intersections as follows:

- 1) Harbour Drive & Crayton Road: Convert to roundabout
- 2) Mooring Line Drive & Crayton Road: Convert to roundabout
- 3) Broad Avenue South & 8<sup>th</sup> Street: Convert to all-way stop control
- 4) 10<sup>th</sup> Avenue South & 9<sup>th</sup> Street: Replace signal, add westbound left-turn lane
- 5) Fleischmann Boulevard & 10<sup>th</sup> Street: Convert to roundabout

A revised control at the Broad Avenue & 9<sup>th</sup> Street intersection that converts the intersection to a three-way stop to improve traffic operations in this corridor was also identified.

Preliminary cost estimates were also prepared for each of the preliminary recommendations. The total cost provided includes each phase for survey, design, construction engineering, as well as a contingency for unexpected items. Therefore, these preliminary costs typically represent a conservative estimate. A copy of the cost estimates for each intersection for this evaluation is provided in Appendix E.

## **EVALUATION MATRIX**

Priority	Intersection	Preliminary Suggestion	Considerations	Preliminary Cost Estimate Construction M,MOT Contingency <u>Survey, Design</u> = TOTAL COST
1	Harbour Drive & Crayton Rd	Roundabout	<ol> <li>Increasing number of multi-modal users (ped/bike)</li> <li>Roundabout has no private Right-of-Way impacts</li> <li>Red-light running observed through intersection</li> <li>Currently long pedestrian crossing distances</li> <li>Roundabout slows each vehicle through intersection</li> <li>More greenspace by removal of turn lanes with roundabout</li> </ol>	\$357,500 \$36,000 \$56,000 <u>\$90,000</u> \$539,500

Appendix A

Crayton Road & Mooring Line Drive Technical Memorandum

## Alternate Street Design, P.A.

## Technical Memorandum

To:	Norman J. Trebilcock, AICP, PE
From:	Michael J. Wallwork, P.E.
Date:	7/24/2015
Re:	Mooring Line Drive at Crayton Road

This technical memorandum has been prepared to detail the capacity analyses, design elements and potential safety benefits of replacing the traffic signals at this intersection with a roundabout rather than upgrading the intersection with mast arms.

### **Capacity Analyses**

The following capacity analyses used traffic counts provided by Trebilcock Consulting Solutions, PA. The analyses were undertaken using SIDRA 6.1 with a copy of the summary sheet for each capacity analysis summary sheet is included in Appendix B. Based on a 1 percent growth rate a one lane roundabout is expected to provide an acceptable level-of-service that would be superior to a signalized intersection, especially in the off-peak hours when the likelihood of a driver having to stop is greatly reduced.

Mooring Line	Time	Level-of-	Average Delay	Volume/	95 <sup>th</sup> Percentile
Roundabout	Period	service	per Vehicle	capacity Ratio	Vehicle Queue (ft)
			(seconds)		and approach
One Lane Roundabout	AM	А	5.2	0.238	36 north
	PM	А	7.4	0.481	91 west
	Saturday Noon	А	6.7	0.405	71 west

### Geometry

The proposed roundabout is a standard one-lane roundabout with a 64-foot diameter refined to match the existing intersection while maintaining low design speeds and accommodating large

1516 Plainfield Avenue, Orange Park, FL 32073 (904) 710-2150 Email: mjwallwork@me.com

trucks. This roundabout layout does not require any right-of-way although is up to the property lines on several corners and will impact some existing landscaping within the pubic right-of-way.

The goal of the roundabout design was to limit vehicle speeds to around 23 mph with lower right turn speeds while accommodating WB-50 trucks. Larger trucks can also pass through or make right turns by using the gutters or partially driving over the truck aprons.

Bike lanes have been provided on all approaches. Bike ramps and shared pathways around the roundabout have been provided so those bicyclists who do not wish to "claim-the-lane" and ride through the roundabout can use the sidewalk system.

Typically a six-foot wide planter strip is used to move the sidewalk and its users away from the roundabout and to provide additional space for landscaping that could include palm trees. To avoid impact on right-of-way the minimum distance recommended by the US Access Board of two feet was provided o several corners.

A copy of the proposed preliminary layout for the roundabout is shown in Appendix B

#### **Roundabout Safety**

#### General

Based on many roundabout studies from the US and around the world roundabouts provide a massive reduction in crashes. A report prepared by the Insurance Institute for Highway safety, found a 90 percent reduction in fatal crashes, most of which are alcohol related, 76 percent reduction in injury crashes and a 39 percent overall reduction in crashes when roundabouts replaced signalized intersections or stop controlled intersections. This study included one, two and three lane roundabouts, well designed and less than well-designed roundabouts. Unfortunately many poorly designed roundabouts have had large increases in crashes due to a lack of adequate speed control.

Other studies on pedestrian safety have shown even greater reductions in pedestrian crashes when compared to signalized intersections. Bicycle crashes are reduced if bicyclists "claim the lane" and ride in front of vehicles and not to their side.

#### Mooring Line Drive/Crayton Road Crash Data

Amazingly this intersection has only had two crashes in five years. This is very low for a signalized intersection. The two crashes that did occur were a left turn crash, which is typical of all signalized intersection, and a driver reversing into the vehicle behind, an unusual crash. Installation of a roundabout would eliminate the possibility of any additional left turn crashes.

#### **Splitter Islands**

One of the very important design elements of roundabouts is the splitter islands or medians on each approach. These islands/medians are very important as they:

- ¥ Direct drivers around the central island,
- ¥ Provide a refuge for pedestrians breaking their crossing in to two parts with the pedestrians only having to cross one direction of traffic at a time.
- ¥ Locate the pedestrian crossing back from the yield line to separate driver decision-making and to provide safer crossings.

#### Landscaping

Mounding the central island and adding vertical elements, trees, public art, clock towers, etc., increase a roundabout's conspicuity so drivers gain advance notice of the need to slow down and drive around the central island. The landscaping can also provide a central feature to enhance the surrounding area. However, it must be done to avoid limitations to sight triangles. Up lighting of the landscaping can enhance the appearance of the roundabout as well as improving its nighttime conspicuity.

#### **Maintenance** Cost

Another benefit of a roundabout is the considerable cost saving on annual maintenance costs which is typically \$3,000 to \$5,000 dollars per year and replacement cost of several hundred thousand dollars every 20 to 30 years.

Maintenance cost of a roundabout can be very low, a few hundred dollars years for weed and litter control typically or several thousand dollars a year for trimming, annual plant changes, mowing of grass, etc.

#### Pedestrians

Signalized intersections are typically quite dangerous of pedestrians as several thousand are killed each year and approximately 15,000 injured each year, (NHSTA). In this case, the problem for pedestrians crossing Mooring Line Drive at the exiting intersection are very long crossings, about 110 feet long. Second, pedestrians must wait for permission to cross at the intersection. At a roundabout pedestrians have the right-of-way and drivers must yield to them. Second, pedestrians only have to cross one lane at a time that is only 15 feet or so wide. The result is greatly enhanced pedestrian safety and mobility.

#### Bicyclists

Signalized intersections can be as or more dangerous for bicyclists as they are for pedestrians. Provided the bicyclists "claim-the-lane" and rides in front of vehicles they should have a safe

ride through the roundabout. If they are uncomfortable doing so, bike ramps and wide sidewalks have been provided around the roundabout.

Level of Service (LOS) Method: Delay & v/c (HCM 2010).

Roundabout LOS Method: Same as Sign Control.

Vehicle movement LOS values are based on average delay and v/c ratio (degree of saturation) per movement

LOS F will result if v/c > 1 irrespective of movement delay value (does not apply for approaches and intersection).

Intersection and Approach LOS values are based on average delay for all movements (v/c not used as specified in HCM 2010). Roundabout Capacity Model: SIDRA Standard.

HCM Delay Formula option is used. Control Delay does not include Geometric Delay since Exclude Geometric Delay option applies. Gap-Acceptance Capacity: SIDRA Standard (Akçelik M3D).

HV (%) values are calculated for All Movement Classes of All Heavy Vehicle Model Designation.

Roynd about, but wow in !	favor as being a
Safentraffic alternative	,
Opposed to must aum at	E-leischmann and
Teath due to cost.	

NAME: JEANNE Feight ADDRESS: PHONE/E-MAIL QUESTIONS OR COMMENTS: HARbour Brive and Mooningline dutersections are in residential oreas - populated by seasonal and retired residents. They have used roundabouts in other states. They are confusing and dangerous - it Dearn't get better with use. The Central Avenue "new" round abouts are just as dispunctional as older nounceabouts. Put in the hunicane proof traffic lights freshings the cross walles and bike lines that is what tax paying residents went.

Thursday, April 13, 2017 4:00 – 7:00 P.M. Naples City Council Chambers

NAME: Juliana Meck ADDRESS: 3 PHONE/E-MAIL QUESTIONS OR COMMENTS: Please make intersections pedestrian friendly Can't tell when light is about to change and I was hit by a car that when I was Crossing because the light changed while I was wattering in front of ear: wasn't hors but was shaken by it. This was intersection

at Mooring line and Crayton (crossing crayton)

- Good idea to convert Broad and 8th to Yway

Stop. Light isn't needed there

Appendix E
